- takes ultrametric gene trees as input
- calculates the probability of species trees that represent all permutations of n putative lineages
- ranks the models using information theory

Species delimitation using Maximum Likelihood

spedeSTEM is a program that delimits species using maximum likelihood and information theory. Specifically, the probabilities of multiple permutations of putative evolutionary lineages are calculated using STEM (Kubatko et al. 2009) and ranked by model probability (see Anderson 2004). spedeSTEM takes as input ultrametric gene trees from multiple loci and an estimate of theta, and returns a table of models ranked by model probability. The web-based software here conducts both discovery and validation analyses, and also generates the set up files and allows the users to subsample alleles from large nexus files. spedeSTEM does not estimate gene trees; for this, we suggest [PAUP](#) or [Garli](#).

About us

Research in the Carstens lab seeks to understand how biological diversity is generated using computational approaches. We investigate empirical systems by identifying the limits of evolutionary lineages, in order to evaluate the relative contributions of evolutionary processes and infer the ecological and environmental forces that have contributed to the formation of population genetic structure.
